

* outcome:

- 1) Transpose of a matrix
- 2) Result of addition, subtraction and multiplication of two matrix

* theory

2 dimension array

→ 2-D array are data structures that organize element in a tabular formate similar to a spreadsheet. They consists of rows and columns where each element is identified by its row index & column

1) Row-major order

$$\text{index} = (i * \text{num cols}) + j$$

where num cols is the number of column in the array

2) Column Major order

~~$$\text{index} = (j * \text{num Rows}) + i$$~~

where num Rows is the number of rows in the array

Matrix operation

1) Addition

To add two matrix their dimensions must be the same. The sum obtained by adding corresponding element of the two

eg

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \quad B = \begin{bmatrix} 5 & 6 \\ 7 & 8 \end{bmatrix}$$

$$A+B = \begin{bmatrix} 6 & 8 \\ 10 & 12 \end{bmatrix}$$

2) Subtraction
Subtraction of matrix is similar to addition, where corresponding elements are subtracted

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \quad B = \begin{bmatrix} 5 & 6 \\ 7 & 8 \end{bmatrix}$$

~~$$A-B = \begin{bmatrix} -4 & -4 \\ -4 & -4 \end{bmatrix}$$~~

3) Multiplication

To multiply two matrix $A(m \times n)$ and $B(n \times p)$.
The number of column in A must be equal to the number of rows in B . The resultant product matrix will have dimensional $m \times p$.

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \quad B = \begin{bmatrix} 5 & 6 \\ 7 & 8 \end{bmatrix}$$

$$A \times B = \begin{bmatrix} 1 \cdot 5 + 2 \cdot 7 & 1 \cdot 6 + 2 \cdot 8 \\ 3 \cdot 5 + 4 \cdot 7 & 3 \cdot 6 + 4 \cdot 8 \end{bmatrix} = \begin{bmatrix} 19 & 22 \\ 45 & 50 \end{bmatrix}$$

- Transpose of matrix is obtained by interchanging it's row and column if A is an $n \times n$ matrix it will be an $n \times m$ matrix

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix} \quad A^T = \begin{bmatrix} 1 & 4 \\ 2 & 5 \\ 3 & 6 \end{bmatrix}$$

Algorithm:

- * Step 1) Start
- * Step 2) Input number of rows & column of first matrix
- * Step 3) Input element of first matrix
- * Step 4) Input number of rows & column of second matrix
- * Step 5) Input element of second matrix
- * Step 6) Function to transpose first i.e. the element at row column C in the original is placed at row column R of the transpose two matrix
- * Step 7) Function to add - Subtract and multiply two matrix
- * Step 8) Stop

* Flowchart

(Start)

Input row & column of matrix 1

Input element of matrix 1

Input row & column of matrix 2

Input element of matrix 2

Transpose matrix 1

Add matrix, subtract

multiply matrices

(end)

conclusion

By this way we can perform various operation on matrix successfully.

the elements of a list or array in a specific order typically in ascending or descending order. Sorting can be categorized into main types

- 1) Comparison based sorting
- 2) non-comparison based sorting

- Advantages of sorting

- 1) efficiency in searching
- 2) Improved Data management
- 3) facilities other algorithm

- Disadvantage of sorting

- 1) Time complexity
- 2) space complexity
- 3) overhead

- sorting is a fundamental operation in computer science with various algorithm switched of different contexts

* Selection Sort

Selection sort divides the array into the two part - a sorted and unsorted part. It repeatedly select the smallest (or largest) element from the unsorted part and moves it to the end of the sorted part.

Initial Array : [29. 10. 14. 37. 13]
minimum in 10 swap with 29

Array : [10. 29. 14. 37. 13]
minimum in 13 swap with 29

Array : [10. 13. 14. 29. 37]
minimum in 24 . No swap needed

Array : [10. 13. 14. 29. 37]

Sorted Array

Array: [10, 13, 14, 29, 37]

* Bubble Sort

Bubble Sort repeatedly steps through the list compares adjacent elements & swaps them if they are in the wrong order
This process repeats until the list sorted

Initial Array: [3, 1, 2]

compare 3 > 1 : swap

Array : [1, 3, 2]
compare 3 > 2 : swap

Array : [1, 2, 3]

Array : [1, 2, 3]
compare 2 & 3 : No swap

Array : [1, 2, 3]

* Algorithm

1) Bubble Sort

Step 1) We start from the first element

Step 2) If the second element is greater than first element swap them

Step 3) Then compare second element and third element swap them then are not in the order

Step 4) Continue the process until the last element

Step 5) After the first iteration lack the last element Assuming the last element is the largest so that element doesn't follow the next iteration

2) Selection Sort

Step 1) place pointer on the first element & set as smallest value & is the smallest value

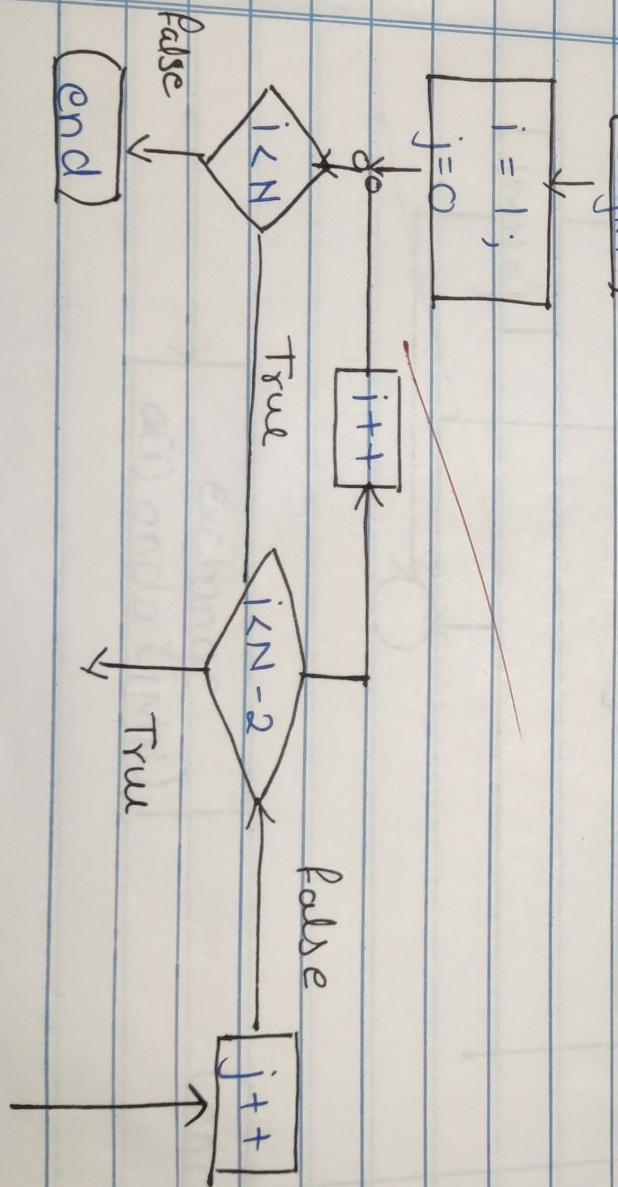

Step 2) compare the second element with the smallest. if the second element is smaller than the value, assign the second element as the

smallest because $8 > 4$. 4 still the smallest
 step 3) compare to third element because
 $1 < 4$ then 1 is the smallest
 step 4) continue compare to last element
 because $5 > 1$ then 1 still the smallest
 steps) swap 1 to the first place that way first
 iteration has been completed and the smallest
 value already saved on the first place. Which
 will not participate in the next iteration
 step 6) Repeat the process of finding the next
 smallest element and swapping it into the
 correct position until the entire array is
 sorted.

* flowchart

1) Bubble sort

(Begin)

$a[i] > a[j+1]$
 temps = $a[j+1]$
 $a[j+1] = a[i]$
 $a[i] = \text{temp}$

Selection Sort

(Begin)

for $i = 0 + 0$ to $n - 2$

$i_{MN} = i$

for $j = i + 1$ to $n - 1$

$i_{MN} = j$

if $a(j) < a(i_{MN})$

exchange
 $a[i]$ and $a[i_{MN}]$

(End)

* Conclusion

By this way we can perform sorting of array using selection and bubble sort
